#### Stepwise selection methods

Use AIC / BIC to score a model  $\mathcal{M}$  – how to optimize over  $\mathcal{M}$ ?

Best subset selection has 2 problems:

- 1. It is often very expensive computationally. We have to fit  $2^p$  models!
- 2. If for a fixed k, there are too many possibilities, we increase our chances of overfitting. The model selected has *high variance*.

#### Stepwise selection methods

# Use AIC / BIC to score a model $\mathcal{M}$ – how to optimize over $\mathcal{M}$ ?

Best subset selection has 2 problems:

- 1. It is often very expensive computationally. We have to fit  $2^p$  models!
- 2. If for a fixed k, there are too many possibilities, we increase our chances of overfitting. The model selected has *high variance*.

In order to mitigate these problems, we can restrict our search space for the best model.

This reduces the variance of the selected model at the expense of an increase in bias.

#### Ridge regression

Ridge regression solves the following optimization:

$$\min_{\beta} \sum_{i=1}^{n} \left( y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{i,j} \right)^2 + \lambda \sum_{j=1}^{p} \beta_j^2$$

In blue, we have the RSS of the model.

In red, we have the squared  $\ell_2$  norm of  $\beta$ , or  $\|\beta\|_2^2$ .

The parameter  $\lambda$  is a tuning parameter. Use cross-validation.

#### The Lasso

Lasso regression solves the following optimization:

$$\min_{\beta} \sum_{i=1}^{n} \left( y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{i,j} \right)^2 + \lambda \sum_{j=1}^{p} |\beta_j|$$

In blue, we have the RSS of the model.

In red, we have the  $\ell_1$  norm of  $\beta$ , or  $\|\beta\|_1$ .

The parameter  $\lambda$  is a tuning parameter. Use cross-validation.

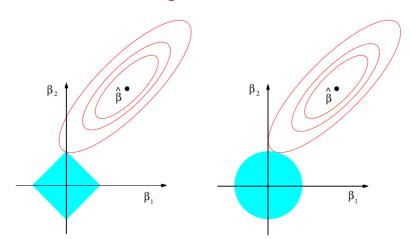

# Ridge / LASSO / Best subset

▶ **Ridge:** for every  $\lambda$ , there is an s such that  $\hat{\beta}_{\lambda}^{R}$  solves:

▶ Lasso: for every  $\lambda$ , there is an s such that  $\hat{\beta}_{\lambda}^{L}$  solves:

Best subset:

#### Ridge vs. LASSO

#### The Lasso

 $\bullet: \quad \sum_{j=1}^{p} |\beta_j| < s$ 

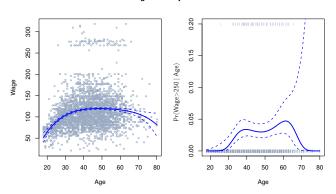

#### Ridge Regression

 $\sum_{j=1}^{p} |\beta_j| < s$ Best subset with s = 1 is union of the axes...

## Non-linear regression

Problem: How do we model a non-linear relationship?

#### Degree-4 Polynomial

Left: Regression of wage onto age.

**Right:** Logistic regression for classes wage > 250 and wage  $\le 250$ 

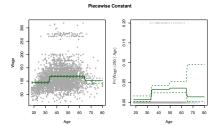

#### Basis functions

#### Strategy:

Define a model:

$$Y = \beta_0 + \beta_1 f_1(X) + \beta_2 f_2(X) + \dots + \beta_d f_d(X) + \epsilon.$$

- Fit this model through least-squares regression:  $f_j$ 's are nonlinear, model is linear!
- ▶ Options for  $f_1, \ldots, f_d$ :
  - 1. Polynomials,  $f_i(x) = x^i$ .
  - 2. Indicator functions,  $f_i(x) = \mathbf{1}(c_i \le x < c_{i+1})$ .

#### Smoothing splines

Find the function f which minimizes

$$\sum_{i=1}^{n} (y_i - f(x_i))^2 + \lambda \int f''(x)^2 dx$$

- ▶ The RSS of the model.
- A penalty for the roughness of the function.

## Local linear regression

To predict the regression function f at an input x:

- 1. Assign a weight  $K_i(x)$  to the training point  $x_i$ , such that:
  - $K_i(x) = 0$  unless  $x_i$  is one of the k nearest neighbors of x.
  - $K_i(x)$  decreases when the distance  $d(x, x_i)$  increases.
- 2. Perform a weighted least squares regression; i.e. find  $(\beta_0, \beta_1)$  which minimize

$$\hat{\beta}(x) = \operatorname{argmin}_{(\beta_0, \beta_1)} \sum_{i=i}^{n} K_i(x) (y_i - \beta_0 - \beta_1 x_i)^2.$$

3. Predict  $\hat{f}(x) = \hat{\beta}_0(x) + \hat{\beta}_1(x)x$ .

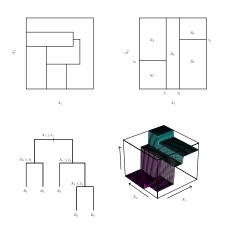

## GAM - generalized additive model

Fit a model with regression function of the form

$$f(X_1, \dots, X_p) = \sum_{j=1}^p f_j(X_j)$$

Each term can be a local regression or smoothing spline

#### Decision trees, 10,000 foot view

- 1. Find a partition of the space of predictors.
- 2. Predict a constant in each set of the partition.
- The partition is defined by splitting the range of one predictor at a time.
  - $\rightarrow$  Not all partitions are possible.

# Bagging

► In Bagging we average the predictions of a model fit to many Bootstrap samples.

Example. Bagging the Lasso

- Let  $\hat{y}^{L,b}$  be the prediction of the Lasso applied to the bth bootstrap sample.
- ▶ Bagging prediction:

$$\hat{y}^{\mathsf{boot}} = \frac{1}{B} \sum_{b=1}^{B} \hat{y}^{L,b}.$$

#### Boosting

- 1. Set  $\hat{f}(x) = 0$ , and  $r_i = y_i$  for  $i = 1, \ldots, n$ .
- 2. For  $b = 1, \ldots, B$ , iterate:
  - **2.1** Fit a decision tree  $\hat{f}^b$  with d splits to the response  $r_1, \ldots, r_n$ .
  - 2.2 Update the prediction to:

$$\hat{f}(x) \leftarrow \hat{f}(x) + \lambda \hat{f}^b(x).$$

2.3 Update the residuals,

$$r_i \leftarrow r_i - \lambda \hat{f}^b(x_i).$$

3. Output the final model:

$$\hat{f}(x) = \sum_{b=1}^{B} \lambda \hat{f}^b(x).$$

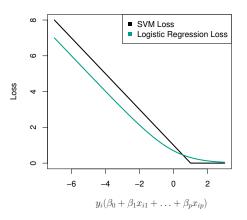

# Boosting vs. bagging (in a nutshell)

- 1. Bagging averages over a random collection of trees.
- 2. Boosting is "gradient descent" in a space of "trees".

# Support vector machine

- 1. Relaxation of maximum margin classifier.
- 2. Dual problem involves only the kernel matrix  $K(x_i, x_i)$ .
- 3. Can be replaced with a "kernel": radial basis function, polynomial, etc.

## Support vector machine

1. Similar to logistic regression but uses *hinge loss*.

#### Regression methods

- Nearest neighbors regression
- Multiple linear regression
- ► Stepwise selection methods
- ► Ridge regression and the Lasso
- Principal Components Regression
- Partial Least Squares
- Non-linear methods:
  - Polynomial regression
  - Cubic splines
  - Smoothing splines
  - Local regression
  - ► GAMs: Combining the above methods with multiple predictors
- Decision trees, Bagging, Random Forests, and Boosting

#### Classification methods

- Nearest neighbors classification
- Logistic regression
- LDA and QDA
- Stepwise selection methods (for logistic)
- Decision trees, Bagging, Random Forests, and Boosting
- Support vector classifier and support vector machines

## Self testing questions

For each of the regression and classification methods:

- 1. What are we trying to optimize?
- 2. What does the fitting algorithm consist of, roughly?
- 3. What are the tuning parameters, if any?
- 4. How is the method related to other methods, mathematically and in terms of bias, variance?
- 5. How does rescaling or transforming the variables affect the method?
- 6. In what situations does this method work well? What are its limitations?
